ABSTRACT
Speech recognition (SR) technologies were evaluated in different classroom environments to assist students to automatically convert oral lectures into text. Two distinct methods of SR-mediated lecture acquisition (SR-mLA), real-time captioning (RTC) and post-lecture transcription (PLT), has been developed to increase the word recognition accuracy. Both methods have been compared according to technical feasibility and reliability of classroom implementation, instructors’ experiences, word recognition accuracy, and student class performance. RTC provided near-instantaneous display of the instructor’s speech for students during class. PLT employed a user-independent SR algorithm to optimally generate multimedia class notes with synchronized lecture transcripts and instructor audio for students to access online after class. It has been learnt that PLT provides more word recognition accuracy than RTC. The potential benefits of SR-mLA for students who have difficulty taking notes accurately and independently were discussed, particularly for non-native English speakers and students with disabilities.

Keywords

1. INTRODUCTION
Speech recognition (SR) technology has a burgeoning range of applications in education system from captioning video, television for the hearing-impaired, voice controlled computer operation, till dictation. Some of the most popular commercially available applications of SR are for dictation and other hands-free writing tasks with software applications, such as Dragon NaturallySpeaking™ (Nuance Communications®) and IBM® ViaVoice™. The commercial SR tools are commonly said to achieve 98% accuracy but for the spontaneous speech the accuracy cannot be achieved in the same way due to number of reasons [1]. Liberated Learning Consortium (LL) (www.liberatedlearning.com) and its members have done research for the past decade and demonstrated that standard commercially available SR software was unsuitable for real-time captioning or transcription of speech [1]. Transcripts produced from a continuous unbroken stream of text are additionally difficult to read and interpret without punctuation or formatting [2], [3].

These SR technologies have been applied to automatically transcribe instructor’s lecture and process the transcription to acquire near verbatim lecture transcripts for students [4], [5], [6]. The benefits of producing lecture transcripts have shown to enhance both learning and teaching. Students could make up for missed lectures as well as to corroborate the accuracy of their own notes during the lectures they attended. Coupled with a recorded audio/video lecture track and copies of the lecture slides, students could re-create the lecture material for replicating the lecture at their own learning pace. These lecture transcripts and additional multimedia recordings also enable instructors to review their own teaching performance and lecture content to assist them to improve individual pedagogy [4]. Likewise, SR has been used for quickly searching certain keywords in order to retrieve specific text or video lecture content [7], [8].

In this study, comparison has been done on the classroom implementation, reliability, and academic performance impact of two different methods of SR-mediated lecture acquisition (SR-mLA). Both SR-mLA techniques were employed using conventional educational technology. The first method of SR-mLA provided real-time captioning (RTC) of an instructor’s lecture speech using a client-server application for instant viewing during class on a projection screen or directly to the students’ laptop personal computers (PCs). The second SR-mLA method, post-lecture transcription (PLT), employed a digital audio recording of the instructor’s lecture to provide transcripts, which were synchronized with the audio recording for students to view online or download after class. These studies were conducted in courses other than science, technology, engineering, and mathematics (STEM) and did not attempt to quantitatively measure the effects of providing SR-based lecture notes on student class performance [4], [5], [6]. Though SR has been used for academic purposes related to text searching and retrieval of lecture content [7], [8], to our knowledge class performance using SR-mLA has not been quantitatively evaluated before. The relevance of SR-mLA tools for instructors and students, particularly those with special needs, were discussed in detail for future study.

2. A LITERATURE SURVEY ON EXISTING SYSTEM

2.1 Liberated Learning Consortium (LL)
The LIBERATED LEARNING PROJECT (LLP) is an applied research project studying two core questions: 1) Can speech recognition (SR) technology successfully digitize lectures to display spoken words as text in the classrooms? 2) Can speech recognition technology be used successfully as an
alternative to traditional classroom notetaking for persons with disabilities? This paper addresses these intriguing questions and explores the underlying complex relationship between speech recognition technology, university educational environments, and disability issues.

**MERITS:**
1. It can achieve 98% accuracy.

**DEMERTS:**
1. The accuracy of spontaneous speech cannot be assessed.
2. Standard commercially available SR software was unsuitable for real-time captioning or transcription of speech.

2.2 **Liberated Learning Initiative (LLI)**

Creative uses for both mainstream and adaptive technologies are proliferating in higher education. Accordingly, there are continued opportunities to evaluate how technology may be used to enhance accessibility, facilitate inclusion, offer innovative learning alternatives, and ultimately promote academic success for students with disabilities (SWD). Historically, students with disabilities have experienced inadequate access to lecture material in the classroom, and insufficient access to the academic resources necessary to sustain their progress. The Liberated Learning Initiative (LLI) has been committed to understanding how speech recognition technology (SR) may contribute to creating a barrier-free learning environment for students.

**MERITS:**
1. The benefits of producing lecture transcripts have shown to enhance both learning and teaching.
2. Coupled with a recorded audio/video lecture track and copies of the lecture slides, students could re-create the lecture material for replicating the lecture at their own learning pace.

**DEMERTS:**
1. Transcripts produced from a continuous unbroken stream of text are additionally difficult to read and interpret without punctuation or formatting.

2.3 **High School Pilot Project**

This research concentrated on evaluating how the technology might enhance accessibility, facilitate inclusion and promote academic success for students with disabilities. The Liberated Learning Project, used a collaborative model with IBM and other telecommunication company to explore the use of SR as an accessibility technology in the classroom. Their concept was relatively simple; a professor’s lectures would be digitized and displayed on a screen in real time and the digitized lectures would be made available for students after the lecture on-line. It was believed from the start that this combination of access would be helpful for students who are deaf, hard of hearing, learning disabled or mobility impaired. Furthermore, the provision of post-lecture edited online notes would be superior to the conventional dependence on other persons to take notes for those who could not take their own lecture notes.

**MERITS:**
1. It would be helpful for students who are deaf, hard of hearing, learning disabled or mobility impaired.

**DEMERTS:**
1. There was inherent need and obligation of SRT on non-disabled students and on pedagogy and teachers.

2.4 **SR-mLA technique using IBM tools**

2.4.1 **Two Approaches for SR-mLA:**

In this study, based on comparison done on the classroom implementation, reliability, and academic performance impact two different methods of SR-mediated lecture acquisition (SR-mLA) was developed. The first method of SR-mLA provided real-time captioning (RTC) of an instructor’s lecture speech using a client-server application for instant viewing during class on a projection screen or directly to the students' laptop personal computers (PCs). The second SR-mLA method, post-lecture transcription (PLT), employed a digital audio recording of the instructor’s lecture to provide transcripts, which were synchronized with the audio recording for students to view online or download after class.

Instructors teaching large lecture classes were used to wearing wireless microphones for voice amplification. The generated lecture transcripts were made available to student to access online later. The most time consuming task of lecture transcripts was editing for errors. Error correction serves two purposes; (1) to improve the readability of the lecture transcripts for student use and (2) to enhance the accuracy of future SR for speaker voice profile improvements and building better acoustic and language models to be shared with other LL Consortium members.[23]. Compared to RTC with ViaScribe, PLT using HTS was found easier to implement, requiring no prior speaker training, and resulted in more than a 6% improvement in word recognition accuracy. Under favorable conditions for continuous SR applications, such as reading selected materials, trained users could achieve very high word recognition accuracy[1]. ViaScribe resulted in decreased word recognition accuracy than PLT for the same instructor in the same course. However, ViaScribe had problem running consistently during class due to operating system compatibility issues.

**Table 1** show summarizes and compares major technical functionalities between real-time captioning using ViaScribe and post-lecture transcription using HTS.

**Table 1. Comparison of Major Functionalities between ViaScribe and HTS System**

<table>
<thead>
<tr>
<th>Features</th>
<th>ViaScribe (RTC)</th>
<th>HTS (PLT)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Recording method</td>
<td>ViaScribe has built capability of recording through classroom PC that receives audio from the wireless headset microphone worn by the lectures.</td>
<td>This system runs software on classroom PC that records lecture audio in SR-compatible format.</td>
</tr>
<tr>
<td>User dependent independent SR engines</td>
<td>Initial user-specific profile training is necessary for the lectures to accustom SR-software to speakers voice to maximum word recognition accuracy.</td>
<td>No user training is required. The speaker wears a high-quality microphone to record the lecture audio file.</td>
</tr>
<tr>
<td>Error correction</td>
<td>After the lecture, the generated raw transcript can be corrected in order to update user’s voice profile continuously.</td>
<td>The recorded audio file is uploaded to the HTS website via user interface for transcription and error correction.</td>
</tr>
<tr>
<td>Display method</td>
<td>Classroom PC’s runs server software to transmit the transcripts to students laptop PC’s, connected to client and also on classroom projection screen.</td>
<td>Lecture audio is synchronized with the PPT’s and diagrams which are provided as multimedia class notes.</td>
</tr>
</tbody>
</table>
2.4.1.1 IBM® ViaScribe: IBM® ViaScribe utilized a SR engine capable of transcribing live or pre-recorded speech developed collaboratively by IBM® and the LL Consortium. During class lectures displayed or captioned what the instructor uttered into text as it is being spoken. ViaScribe was chosen for real-time captioning, because it had a proven track record by LL members for reliable captioning and had a client-server platform for streaming live transcription to students’ laptop PCs during lectures [3], [4], [21].

2.4.1.2 IBM® Hosted Transcription Service (HTS): IBM® HTS was selected for post-lecture transcription primarily because of its higher word recognition accuracy rates compared to other systems, hence was found suitable for recognizing extemporaneous speech [22]. HTS is a speaker-independent SR system developed by IBM Research that automatically transcribes a variety of standard audio or video file formats through a cloud service. HTS’ SR engine employs a double-pass decoding technique, which dynamically adjusts to the speaker’s voice, without requiring voice profile training or enrollment [22].

MERITS:
1] Improve the word recognition accuracy through speaker-dependent and speaker-independent SR systems developed by IBM Research.

DEMERITS:
2] These SR-mLA techniques developed by IBM Research group are too costly to afford and use.

2.5 Implications for Student Learning:
Past studies have demonstrated that acquiring and studying lecture notes resulted in a greater learning experience and higher overall academic performance for students [17], [18],[24]. Students had stated that they benefited the most from having multimedia class notes by: 1) being able to pay more attention to the instructor instead of focusing on recording complete class notes, 2) the ability to review the lecture material multiple times, 3) synchronization of the instructor’s lecture audio, transcripts, and slides, and 4) ability to make notes, comments, remarks and dynamically search for specific lecture keywords, time periods, or slides in these multimedia notes.

SR-mLA was believed that it would be especially advantageous for students with special needs, such as non-native English-speaking students and students with disabilities, to obtain class notes without having to rely upon classmates or paid notetakers or captionists [4], [5], [6], [25]. Students incapable of or not confident in their own notetaking are able to acquire through PLT accurate and comprehensive multimedia class notes, which they could review at their own convenience and pace [16].

[24]: Researchers were interested in academic self-regulated learning have begun to study processes that students use to initiate and direct their own notetaking. The participants were both native speakers of English (L1) and English as a second language students enrolled in an information systems course (Total N=160). After an initial training period, it was observed that an L2 lecturer in information systems delivered three 2-hour lectures over a three-week period to the participants and other students. Compared with L1 students, a significantly greater number of L2 students and special needs students reported that the system had potential as an instructional support mechanism. However, a greater accuracy in the system’s recognition of lecture text vocabulary needs to be achieved.

[7]: The number of digital lecture video recordings has increased dramatically since recording technology became easier to use and searching within this large archive are limited and difficult. Additionally, detailed browsing in videos is not supported due to the lack of an explicit annotation. Manual annotation and segmentation is time-
3. BACKGROUND

3.1 Notetaking for students with special needs

Though audio recording of class notes is easily achieved with a student tape recorder or a classroom recording system provided through the school, acquiring the actual text transcripts of class lectures was vitally important. The addition of text transcripts versus purely audio enhances accessibility [9], [10]. Students with learning disabilities may have difficulty with both aspects of lecture-to-lecture note translation [1], [2], [3]. The automatic SR-mLA approaches do not depend on the current standard of employing a captionist to caption instructor’s speech into text during class or notetaking services for writing lecture notes [11], [12]. For students with significant hearing loss, captions are traditionally employed to interpret and transcribe what the instructor is lecturing [11]. Likewise, students with mobility (i.e. quadriplegia/ tetraplegia), learning (dyslexia, attention deficit disorders), or sensory (low vision, hard of hearing) impairments may not be able to take notes by themselves and must rely on hired notetakers to acquire lecture notes [13], [14]. SR-mLA has been shown to help international students who are non-native speakers with regard to the language of instruction (in this case English) to acquire accurate lecture notes [5], [16].

[9]: Multimedia has become technically easier to create (e.g. recording lectures) but while users can easily bookmark, search, link to, or tag the WHOLE of a podcast or video recording available on the web they cannot easily find, or associate their notes or resources with, PART of that recording.

[10]: Although manual transcription and captioning can increase the accessibility of multimedia for deaf students it is rarely provided in educational contexts due to the cost and shortage of highly skilled and trained stenographers. Speech recognition has the potential to reduce the cost and increase the availability of captioning if it could satisfy accuracy and readability requirements.

[11]: Deaf and hard of hearing people can find it difficult to follow speech through hearing alone or to take notes when lip-reading or watching a sign-language interpreter. Lectures can be digitally recorded and replayed to provide multimedia revision material for students who attended the class and a substitute learning experience for students unable to attend.

[13]: Federal legislation requires that supplementary aids and services should be provided to students with diagnosed disabilities to assist them in accessing the general-education curriculum. Such modifications to the curriculum may include assistive technology (AT) devices and services. AT can be any item, piece of equipment, or teacher-made product that is designed to improve a student’s functional capability or help a student succeed in accessing the general education curriculum.

[15]: Listening to a speech recording was found more difficult than visually scanning a document because of the transient and temporal nature of audio. Audio recordings capture the richness of speech, yet it was difficult to directly browse the stored information. This article describes techniques for structuring, filtering, and presenting recorded speech, allowing a user to navigate and interactively find information in the audio domain. This article
describes the Speech Skimmer system for interactively skimming speech recordings. Speech Skimmer uses speech-processing techniques to allow a user to hear recorded sounds quickly, and at several levels of detail. [16]: Innovative speech recognition (SR) technology was utilized to assist students acquiring more complete and accurate lecture notes. SR-assisted note-taking can be accomplished in different ways to allow students to devote more attention to understanding course material than manually recording the instructor’s lecture content. Lecture notetaking was physically challenging for many students with disabilities who cannot take notes for the bulk of lecture notes themselves and must rely upon hired notetakers for class notes, which may not readily available or feasible. They are also dependent on the skills and knowledge of the notetaker for the quality of their notes [1].

3.2 Notetaking in STEM subjects
Notetaking was a fundamental and ubiquitous learning activity that students were expected to perform and master during their educational development [17], [18]. The benefits of lecture notetaking include for students to organize, summarize, and better comprehend lecture information, recording content for later studying, self-regulated learning through the active process of notetaking, and simply staying attentive during class [19].

STEM courses, in particular, require substantial notetaking due to the large amount of class information and content specific terminology presented during a relatively short time period. Science courses, such as histology and biochemistry were selected by students as classes they would most want assistance with notetaking [20]. This report describes the effects of making audio podcasts of all lectures in a large, basic biochemistry course promptly available to students. The audio podcasts complement a previously described approach in which a tablet PC is used to annotate PowerPoint slides with digital ink to produce electronic notes that can be archived. The survey data suggest that the students have a positive attitude toward the combination of tablet-based instruction and audio podcasting.

[18]: Previous research had shown that providing written organizational lecture cues boosts notetaking and that boosting notetaking raises achievement. To find out this, participants were made to listen to a lecture that contained or did not contain spoken organizational lecture cues. Participants either recorded lecture notes or refrained from notetaking while listening to the cued or uncued lecture. Results showed that spoken organizational lecture cues boosted the number of noted organizational points and details by 39% and 35%, respectively.

4. PROPOSED SYSTEM
Despite of several documented hurdles of implementing new technologies in classroom settings, it was assumed that it could be feasible to set up and execute RTC and PLT in concert with existing classroom audio-visual equipment and a high-quality microphone during single-instructor. These methods are assumed to be inexpensive and relatively easy to set up prior to class. Both the approaches of SR-mLA would require the following core components: recording hardware and software, SR software, error correction methodology for transcription accuracy, strategy for transcription display, and a usable distribution/publishing platform shown in figure. Both SR-mLA technologies did not interfere with typical lecture teaching activities, only requiring the instructor to wear a wireless microphone.

Fig: Overview of SR-mLA methodology
In this study, we compared the classroom implementation, reliability, and academic performance impact of two different methods of SR-mediated lecture acquisition (SR-mLA). The first method of SR-mLA provided real-time captioning (RTC) of an instructor’s lecture speech using a client-server application for instant viewing during class on a projection screen or directly to the students’ laptop personal computers (PCs). The second SR-mLA method, post-lecture transcription (PLT), employed a digital audio recording of the instructor’s lecture to provide transcripts, which were synchronized with the audio recording for students to view online or download later after the class.

5. CONCLUSION AND FUTURE WORKS
In this survey, we have seen how SR-mLA would help students to improve their academic performance. The next step in evaluating SR-mLA will be to test how students with disabilities can best utilize this technology to achieve particular learning outcomes. Although the initial findings regarding student performance are very encouraging, further research could be done to provide the facility for PowerPoint slides, related diagrams with PLT and also for larger class numbers and multiple courses is required to fully understand the impact of SR-mLA on academic performance, particularly for students with special needs. These SR systems can be implemented locally or virtually as a service via cloud computing environment. Access to SR transcription services would be more efficient through local hosting of a SR instance as a cloud service. The cloud computing model “Software as a Service” would allow users to remotely access SR-mLA using internet web browsers. The main advantages of this model are; on demand availability of SR-mLA without any software installation on user systems, access to greater processing power than on local PCs, and automating the whole process of post-lecture transcription from recording the lecture to delivery of multimedia class notes.
